

Programming Fundamentals for Penetration Testing

CompTIA PenTest+ (PT0-003)

Domain: 4.0: Attacks and Exploits

Objective: 4.10: Given a scenario, use scripting to automate attacks.

Video Overview

This video introduces essential programming fundamentals relevant to penetration testing. As you engage with the content, consider how these concepts are not just theoretical but are directly applicable to analyzing and modifying existing code, and how they can empower you to automate various tasks in your future career as a penetration tester. Understanding these basics will also help you interpret proof-of-concept code found online and build your own automation scripts, which are valuable skills in the real world of cybersecurity.

Key Topics Covered

- **Logic Constructs:** Loops ('for', 'while', 'until') for repeating actions and conditional statements ('if', 'then', 'else', 'elif') for decision-making.
- **Operators:** Boolean operators ('and', 'or', 'not') for logical comparisons and arithmetic operators (addition, subtraction, multiplication, division, modulo) for calculations.
- **Data Structures:**
 - **JSON (JavaScript Object Notation):** Organizing data using key-value pairs (dictionaries).
 - **CSV (Comma Separated Values):** Plain text format for separating data with commas.
 - **Lists and Arrays:** Collections of items, with arrays optimized for arithmetic operations and same data types, and lists allowing different data types.
- **Libraries:** Collections of pre-written code modules that can be imported for common tasks.
- **Classes:** Blueprints for creating objects, defining attributes and behaviors.

- **Procedures and Functions:** Reusable blocks of code; functions return a value, while procedures execute commands without returning a value.
